

Imperial burner

The Saadiumm burner is used for melting pieces of solid substance together or heating liquids.

Although the burner is a simple device its use is almost unlimited. The suspension unit is for when one is heating liquids and wants the burner to stay in one place. The variable nozzle can be used for melting large pieces of metal together or for fine work like heating so a substance can bend. It can take either kja or cybear plasma by simply flicking a switch. The trigger lock is so that one doesn't have to hold the trigger down manually.

Plasma containment

The plasma containment can take either kja or cybear plasma. It can be compressed or just normal fill. If it is compressed there must be a special connection to limit the amount of plasma that can come out. The more compressed the plasma is the smaller the connection.
